Abstract

Introduction: Biowaiver procedure, nowadays, is a trend of Modern Biopharmaceuticals. The biowaiver approach based on Biopharmaceutical Classification System (BCS) is intended to replace bioequivalence in vivo studies. Bisoprolol is a medicine most commonly used for heart diseases, the beta blocker family of medications, and is of the β₁-selective type. The Aim of the Study: The aim was to study the dissolution kinetics of bisoprolol tablets to assess their equivalence under conditions in vitro according to the biowaiver. Methods: The study of dissolution kinetics of drugs in the form of bisoprolol tablets has been carried out in accordance with the requirements of the “biowaiver” procedure, the recommendations of the SPhU, and the WHO requirements to assess the possibility of replacing the pharmacokinetic studies in vivo by tests in vitro. Results and Discussion: The possibility to use the recommendations of the “biowaiver” procedure for the registration of generics bisoprolol tablets has been found. The studies conducted have shown that bisoprolol can be referred to Class I of the BCS, i.e., substances with a high biopharmaceutical solubility and a high penetration rate. It will allow conducting comparative studies in vitro to confirm the equivalence of drugs. Conclusions: The evaluated bisoprolol drugs fulfill biowaiver criteria for drugs containing BCS Class I active pharmaceutical ingredients. Both drugs are “rapidly dissolving,” both meet the criteria of dissolution profile similarity, f₂ (i.e., the dissolution profile of the test product is similar to that of the reference product in pH 1.2, 4.5, and 6.8 buffers using the paddle method at 75 rpm), and both are considered to be in vitro equivalent without in vivo evaluation.

Key words: Bisoprolol, dissolution, standardization, tablets

INTRODUCTION

Understanding the process of delivery of drugs to the organ or target cell is one of the tasks of modern pharmacy. In order for the drug to reach the systemic blood flow, it passes through many stages, namely, release from the dosage form, dissolution in the physiological environments of the digestive tract, and absorption through the gastrointestinal membrane. Biowaiver procedure, nowadays, is a trend of Modern Biopharmaceuticals. The biowaiver approach based on Biopharmaceutical Classification System (BCS) is intended to replace bioequivalence in vivo studies.[1-3]

Bisoprolol is a medicine most commonly used for heart diseases, the beta blocker family of medications, and is of the β₁-selective type. Bisoprolol is beneficial in treatment for high blood pressure (hypertension), reduced blood flow to the heart (cardiac ischemia), congestive heart failure, and preventive treatment before and primary treatment after heart attacks, decreasing the chances of recurrence. Its structure is shown in Figure 1. The chemical name is 1-[4-[2-(1-Methylethoxy)ethoxy]methyl]phenoxy]-3-[(1-methylethyl)amino]-2-propanol.

Bisoprolol fumarate used in the product complies with its European Pharmacopoeia monographs. Bisoprolol fumarate is described as very soluble in water and methanol and freely

soluble in alcohol. Ukraine has marketing authorizations for bisoprolol as an immediate-release dosage form in strengths of 2.5, 5, and 10 mg. According to the Caco-2 test results (permeability), bisoprolol appeared to have moderate-to-high permeability. Caco-2 permeability values for bisoprolol are in agreement with BCS Class I and high bioavailability in humans.\textsuperscript{[4-20]}

In Ukraine, bisoprolol tablets are produced by different manufacturers. The aim of our research was to study dissolution kinetics of bisoprolol tablets to assess their equivalence under conditions \textit{in vitro} according to the biowaiver.

**METHODS**

Innovator bisoprolol immediate release tablets, used as reference product, and a generic version (test product) marketed in Ukraine were evaluated. The study of dissolution kinetics was conducted in accordance with the monograph of the SPhU, Supplement 2 “5.N.2. Studies on bioavailability and bioequivalence of generic medicines,” guidance on bioavailability and bioequivalence research,\textsuperscript{[11]} methodological recommendations, as well as the WHO Guide in three media with different pH values: Hydrochloric acid solution with p\textsubscript{H} 1.2, acetate buffer solution with p\textsubscript{H} 4.5, and phosphate buffer solution with p\textsubscript{H} 6.8. All buffer solutions were prepared according to the SPhU.

All dissolution studies were performed using USP Apparatus 2 (Erweka DT 600, Frankfurt, Germany); the device with basket was used; the volume of the dissolution medium - 1000 ml; the temperature of the dissolution medium - 37.0±0.5°C; and the rotation speed of the basket - 100 rpm. Sampling was carried out in 15, 30, and 45 min manually with a 10.0 ml pipette from the plot midway between the surface of the dissolution medium and the basket at the distance of 2 cm from the wall of the dissolution vessel. The samples obtained were filtered through a filter paper with the pore size of from 2 to 3 μm. 5.0 ml of the filtrate obtained was diluted to the volume of 100.0 ml with the corresponding dissolution medium. The volume selected was compensated by the corresponding dissolution medium. To obtain statistically reliable results, the test was carried out on 12 samples of each of the study objects. Drug release was assayed using high-performance liquid chromatography (Agilent 1260). Twelve tablets of each preparation were studied to obtain statistically significant results. Dissolution profile comparisons were made according to the WHO guidelines (1). Statistical treatment was carried out using Microsoft Excel software. The equivalence of dissolution kinetics of drugs in the form of bisoprolol tablets was assessed by the value of the similarity factor (f\textsubscript{2}), which should be from 50 to 100, to make a conclusion about conformity of the kinetic curves. For each time interval, the standard deviation of the mean value (SD) was calculated. It must keep the following requirements: Should be <10% starting from the second to the last point of control and <20% for the 1\textsuperscript{st} time point.

**RESULTS AND DISCUSSION**

Biowaiver criteria for drugs containing BCS Class I active pharmaceutical ingredients (1) are as follows:

1. The dosage form is rapidly dissolving (dissolution amount is >85% at 30 min in all media with p\textsubscript{H} 1.2, 4.5, and 6.8) and the dissolution profile of the test product is similar to that of the reference product in p\textsubscript{H} 1.2, 4.5, and 6.8 buffers using the paddle method at 75 rpm or the basket method at 100 rpm and meets the criteria of dissolution profile similarity, f\textsubscript{2} ≥50 (or equivalent statistical criterion).

2. If both the test and the reference dosage forms are very rapidly dissolving (dissolution amount is >85% at 15 min in all media with p\textsubscript{H} 1.2, 4.5, and 6.8 buffers using the paddle method at 75 rpm or the basket method at 100 rpm and meets the criteria of dissolution profile similarity, f\textsubscript{2} ≥50 (or equivalent statistical criterion).

Both evaluated drugs were “rapidly dissolving” [Table 1] because the active pharmaceutical ingredient release at time point 30 min was >85%.\textsuperscript{[21-25]}

Dissolution profiles and corresponding data are shown in Figures 2-4 and Table 1.

On the basis of the data obtained, it has been found that the equivalence of dissolution profiles for all recommended dissolution media is observed (pH 1.2, 4.5, and 6.8) for the drugs studied. In all three dissolution media, the release of bisoprolol is >85% in 15 min [Tables 1 and 2], i.e., the drugs under research can be classified as “highly soluble,” and their equivalence can be determined by the method in vitro. The percent relative standard deviation for all time points fulfills all requirements (≤10% for 15 min and other time points), so results are valid [Table 2]. The studies conducted have shown that bisoprolol can be referred to Class I of the BCS, i.e., substances with a high biopharmaceutical solubility and a high penetration rate. It will allow conducting comparative studies in vitro to confirm the equivalence of drugs.

## CONCLUSIONS

The evaluated bisoprolol drugs fulfill biowaiver criteria for drugs containing BCS Class I active pharmaceutical ingredients. Both drugs are “rapidly dissolving,” both meet
