<sup>1</sup>Department of Pharmaceutical Sciences, Jawaharlal Nehru Technological University, Hyderabad, Telangana, India, <sup>2</sup>Department of Pharmaceutics, Bomma Institute of Pharmacy, Khammam, Telangana, India, <sup>3</sup>Department of Pharmaceutics, Vagdevi College of Pharmacy, Warangal, Telangana, India

## Abstract

**Aim:** The purpose of the present study was to understand the effect of formulation variables of lipid solid dispersion on the dissolution of a model drug, rivaroxaban. **Method:** A three-factor, three-level Box–Behnken design was used to explore the main and interaction effect of several independent formulation variables including the amount of Gelucire 48/16 ( $X_1$ ), Compitrol HD5 ATO ( $X_2$ ), and Labrasol ( $X_3$ ). Particle size ( $Y_1$ ) and dissolution percentage of rivaroxaban ( $Y_2$ ) were the dependent variables. **Statistical Analysis:** A mathematical relationship was obtained to explain the effect of all factors and their colinearities on the dissolution of rivaroxaban. **Results:** A formulation optimization was then performed to maximize dissolution percentage of rivaroxaban ( $Y_2$ ). The optimized formulation was predicted to dissolve 62.4% of rivaroxaban at 5 min, when  $X_1$ ,  $X_2$ , and  $X_3$  values were 20.0, 30.0, and 2.0 mg, respectively. **Conclusion:** In conclusion, the Box–Behnken experimental design allowed us to understand the effect of formulation variables on the dissolution of rivaroxaban from lipid solid dispersion, and optimize the formulation to obtain drug dissolution.

**Key words:** Box–Behnken design, compitrol HD5 ATO Labrasol, dissolution, Gelucire 48/16, Rivaroxaban, lipid solid dispersion

## INTRODUCTION

Rivaroxaban drug used in acute coronary syndrome, prevention of cardiovascular death, myocardial infarction and stent thrombosis.<sup>[1]</sup> Rivaroxaban is a potent selective oral direct factor Xa inhibitor, it belongs Biopharmaceutics Classification System Class II drug, having low solubility and high permeability. Therefore, the limited aqueous solubility (20.0  $\mu\text{g/mL}$ ) of rivaroxaban is the main hurdle of its *in vitro* dissolution profile, and thus the oral bioavailability. Depending on the choice of excipient(s) and formulation techniques, it is possible to obtain a variety of systems including physical mixtures, liquid/solid solutions, solid dispersions, and self-micro or self-nano emulsifying drug delivery systems.<sup>[2]</sup> Lipid-based formulations including lipid solid dispersion formulations offer the potential for enhancing the dissolution and absorption of poorly soluble and/or poorly permeable compounds. Lipid solid dispersions

are one of the most successful formulations to improve the *in-vitro* dissolution and *in-vivo* absorption of poorly soluble drugs and their bioavailability.<sup>[3]</sup>

The dissolution of drug from lipid solid dispersion is controlled by the relative amount of combinations of hydrophilic lipids in the formulation. However, it is time-consuming to obtain an optimized formulation with rapid and complete dissolution by traditional formulation screening and optimization process. The application of statistical experimental design to pharmaceutical formulation development has been demonstrated to be efficient and satisfactory to acquire the necessary information to understand the relationship between independent and dependent variables in a formulation.

Response surface methodology (RSM) is often used when only a few significant factors are involved in optimization. Box–Behnken design, one of RSM design, was applied herein because it requires fewer runs (17 runs) in a three-factor experimental design among all the RSM designs and is particularly useful when extreme treatment combinations should be avoided.<sup>[4]</sup> The independent variables for the present study were the following: The amount of Gelucire 48/16 ( $X_1$ ), Compitrol HD5 ( $X_2$ ) and Labrasol ( $X_3$ ). The dependent variables included drug dissolution profile and particle size. As part of the optimization process, the main effects, interaction effects and quadratic effects of the formulation ingredients were investigated to understand the factors influencing the dissolution of rivaroxaban from the lipid solid dispersion. Spray drying method was chosen for the preparation of solid dispersions.<sup>[5]</sup> The spray drying method was selected for the preparation of rivaroxaban lipid solid dispersion, which were formulated by dissolving accurately weighed amounts of rivaroxaban, Gelucire 48/16, Compitrol HD5 and Labrasol in dichloromethane (DCM) processed for spray drying and collects the dried sample from the drying chamber, cyclone 1 and cyclone 2 then dried material was packed in an airtight container.<sup>[6]</sup>

## MATERIALS AND METHODS

### Materials

Rivaroxaban drug was obtained as gift sample from MSN Laboratories, Hyderabad, India. Macrogol stearate polyoxyl stearate (Type I) NF (Gelucire 48/16, HLB = 12), Behenoyl polyoxyl-8 glycerides NF (Compitrol HD5, HLB = 5) and Caprylocaproyl polyoxyl-8 glycerides NF (Labrasol, HLB = 12) provided by Gattefosse (Saint-Priest Cedex, France) as a gift samples. High-performance liquid chromatography (HPLC) grade acetonitrile and phosphoric acid were purchased from Tedia. Co., Ltd. (Fairfield, OH, USA). Gelatin capsules (size 1) were obtained from ACG Capsules. (Mumbai, Maharashtra, India). Reagents were of analytical grade, and preparation of HPLC mobile phase was done with Millie-Q demineralized double-distilled water.

### Methodology

#### Formulation of rivaroxaban lipid solid dispersion

The preparation method includes the dispersion of rivaroxaban in the lipid matrix consisting of Gelucire 48/16, Compitrol HD5 and Labrasol at different weight ratios. The drug dispersed lipid matrix is dissolved in the DCM to obtain a clear solution. The ratio of lipids in the optimized and finalized composition present in the ratio of 10:15:1 of Gelucire 48/16, Compitrol HD5 and Labrasol, respectively. The resulting solution was subjected to spray drying using Labultima spray dryer. The total solid contents concentration

was maintained at 5 w/v %. The dried rivaroxaban drug loaded lipid-solid dispersions were collected from the vessel, solid mass was grounded and passed through sieve no. 100 and stored in desiccated environment until further study.

To develop free flowing fine particles by spray drying method, different adsorbents were selected and evaluated.<sup>[7,8]</sup> The flow properties of resulting dried powder from the trails Gelucire 48/16 in combination with Compitrol HD5 and Labrasol was found to be satisfactory. The optimum drug to excipient(s) ratio was identified on the basis of drug content, drug solubility, and physical form.

### Box–Behnken experimental design

Box–Behnken statistical screening design was used to evaluate main effects, interaction effects, and quadratic effects of the formulation ingredients on the *in vitro* performance of rivaroxaban lipid solid dispersion and optimize the formulation. The non-linear quadratic model generated by the design is of the form:

$$Y = A_0 + A_1X_1 + A_2X_2 + A_3X_3 + A_4X_1X_2 + A_5X_2X_3 + A_7X_1^2 + A_8X_2^2 + A_9X_3^2$$

in which  $Y$  is the measured response of the dependent variables associated with each factor-level combination;  $A_0$  is the intercept;  $A_1$ – $A_9$  are the regression coefficients;  $X_1$ ,  $X_2$  and  $X_3$  are the independent variables studied, which were listed in Table 1. A three-factor, three-level Box–Behnken design was generated by an experimental design software Design-Expert version 9.0 (Statsoft). The amounts of Gelucire 48/16, Compitrol HD5 and Labrasol in each of the 17 formulations were given in Table 2.

Finally, the 17 formulations with different concentrations of Gelucire 48/16, Compitrol HD5 and Labrasol, each containing rivaroxaban at a final loading of 10 mg, were filled into size 1 gelatin capsules. The final drug concentrations in these formulations varied from 16.20% to 24.00%.

### Laser diffraction particle size analysis

The particle size and particle size distribution of the developed formulations are measured using a laser diffraction

**Table 1:** Variables in the Box–Behnken design

| Independent variables                       | Level |        |      |
|---|-------|--------|------|
|   | Low   | Middle | High |
| $X_1$ : Amount of Gelucire 48/16 added (mg) | 15    | 20     | 25   |
| $X_2$ : Amount of Compitrol HD5 added (mg)  | 25    | 30     | 35   |
| $X_3$ : Amount of Labrasol added (mg)       | 1.5   | 2.0    | 2.5  |

PSD: Particle size distribution

size analyzer (HELOS Germany). Samples are suspended in water and two to three drops of isopropyl alcohol is added to disperse the particles and ultrasonicated at 50% amplitude. The particle size and distribution is measured at a measurement range of 10 s in 500 ms time base and at the optimum concentration of 10%.

### Dissolution studies

Dissolution profile performed for rivaroxaban lipid solid dispersion formulations derived from Box-Behnken design. The dissolution rate of rivaroxaban from the prepared lipid solid dispersion (F1 to F17) is measured using a Disso-2000 model dissolution test system (Labindia, India) USP apparatus II (paddle) method in pH 4.5 acetate buffer. The resulted solid dispersion was filled into hard gelatin capsule equivalent to 10 mg of rivaroxaban. In each dissolution vessel, drug-filled capsules are added to 900 ml dissolution medium. Bath temperature and paddle rotation speed are maintained at 37°C and stirred at 75 rpm. Samples were collected periodically and replaced with a fresh dissolution medium. After collection of 30 min sample, recovery study is conducted by stirring the paddle at 200 rpm for 5 min and sample is collected. Samples are filtered through filters (10  $\mu$ m) and analyzed using HPLC.

### Optimization of formulation components

After generating the polynomial equations relating the dependent and independent variables, optimization of

$Y_2$  (dissolution percentage of rivaroxaban at 5 min) was performed using a desirability function to obtain the levels of  $X_1$ ,  $X_2$ , and  $X_3$  which maximized  $Y_2$ .

### Solubility studies

Rivaroxaban solubility in Gelucire 48/16, Compitrol HD5 and Labrasol were measured as follows: Excess amount of Rivaroxan was added into cap tubes each containing 1 g of each component and slightly heated. After sealing, the tubes were shaken with an isothermal shaker (Taicang Laboratorial Equipment Factory, Jiangsu, China) at 37°C for 72 h. After reaching equilibrium, each tube was centrifuged at 10,000 g for 10 min.

An appropriate amount of the samples were taken from the supernatant and then diluted with acetonitrile. The concentrations of rivaroxaban were then determined by the HPLC method as shown in Table 3.

## RESULTS AND DISCUSSION

### Saturation solubility of drug in lipid component

Saturation solubility performed for drug in lipid component, and saturation solubility is shown in Table 3.

Rivaroxaban shows good solubility in Gelucire 48/16 and Labrasol as compare to the Compitrol HD5. The rivaroxaban

incorporated solid-lipid dispersions are prepared dissolving the drug, Gelucire 48/16, Compitrol HD5 and Labrasol in dichloromethane (DCM) and processed for spray drying with the optimized process parameters and collects the dried sample from the drying chamber, cyclone 1 and cyclone 2. By preparing the rivaroxaban incorporated solid lipid particles, it is assumed to have a higher aqueous dissolution of the drug due to the morphological conversion of the drug, hydrophilic lipids and reduced particle size.

A series of experiments were then conducted based on the generated Box–Behnken design. The observed responses for the 17 formulations are given in Table 2. To avoid the possible undesirable interaction, the dissolution tests were carried out immediately after the loading of contents. The dissolution profiles of the 17 formulations were presented in Table 4a and b and Figure 1a-c.

Although all formulations demonstrated a full dissolution of rivaroxaban at 30 min, the dissolution percentage of rivaroxaban at 5 min varied from 42.70% to 64.70% with no particular pattern being found.

The mathematical relationship in the form of a polynomial equation for the measured response,  $Y_2$ , is listed below. The above equation represents the quantitative effect of independent

variables ( $X_1$ ,  $X_2$ , and  $X_3$ ) and their interactions on the response ( $Y_2$ ). Concerning the  $P$  value of the coefficients,  $X_{12}$ ,  $X_2$ ,  $X_{22}$  and  $X_1X_3$  were found to have a significant effect on  $Y_2$ . The theoretical values of  $Y_2$  were obtained by substituting the values of  $X_1$ - $X_3$  into the above equation, which was in reasonably good agreement with the observed values as shown in Table 5.

The model fit summary statistics given in Table 6, and the model suggested the design is quadratic. The analysis of variance (ANOVA) for  $Y_2$  was summarized in Table 7. With all the  $P < 0.05$ , we further confirmed that the linear, square and interaction effect of the independent variables were significant in predicting the response ( $Y_2$ ). The relationship between the dependent and independent variables was further elucidated using contour plots.

The effect of  $X_1$  and  $X_2$  and their interaction on  $Y_2$  at a middle level of  $X_3$  is given in Figure 2. As illustrated in Figure 2, when the amount of Gelucire 48/16 ( $X_1$ ) increased from 15 to 25 mg and Compitrol HD 5 ( $X_2$ ) increased from 25 to 35 mg, the dissolution at 5 min ( $Y_2$ ) increased to a certain level and then decreased to original value. This phenomenon might be explained by the action mechanism of Gelucire 48/16 and Compitrol HD5 in the lipid solid dispersion. Compitrol HD5 having a low HLB value, drug release from the formulation retard as the concentration of Compitrol HD5 increased after a particular concentration, result in decrease the dissolution.

Figure 3 response surface plots (three-dimensional) showing the effect of the amounts of Gelucire ( $X_1$ ) and Labrasol ( $X_3$ ) on the response dissolution at 5 min ( $Y_2$ ). Thus, at low Gelucire 48/16 concentration, the increased amount of Gelucire 48/16 favored the drug dissolution by emulsifying action of Gelucire 48/16 might be

responsible for the improvement in drug release properties from the prepared solid dispersions. At higher level of Gelucire 48/16, the formation of liquid crystal was observed. The role of added Gelucire 48/16 ( $X_1$ ) and its interaction with Labrasol ( $X_3$ ) on rivaroxaban dissolution at 5 min ( $Y_2$ ) can be discussed with the help of Figure 3. As shown in this Figure 3, with a low level of the Gelucire 48/16 added,  $Y_2$  levels increased from 46.80 to 64.70% when  $X_3$  increased from 1.5 to 2.5 mg, while  $Y_2$  decreased from 58.90% to 47.70% at high  $X_1$  with the same increase in  $X_3$ .

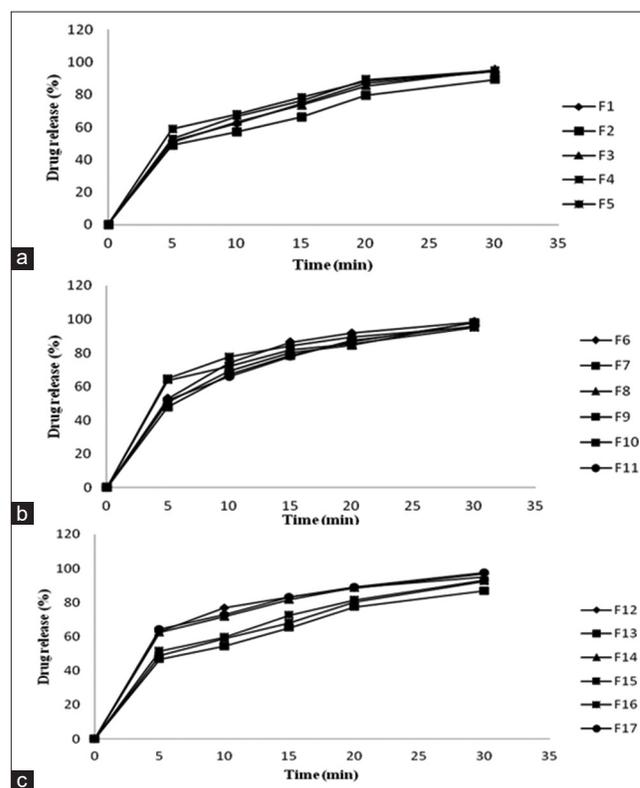

Hence, it is clear that the ratio of Gelucire 48/16 and Labrasol has a major effect on the dissolution percentage of rivaroxaban at 5 min, which is in agreement with the obtained  $P$  value of the coefficient of  $X_1X_3$ .

Figure 4 showed the effect of  $X_2$  and  $X_3$  and their interaction on  $Y_2$  at a middle level of  $X_1$ . As shown in Figure 4, at all levels of Labrasol,  $Y_2$  levels underwent an increase and then decrease when  $X_2$  increased from 25 to 35 mg, which can be explained by the formation of lipid matrix at higher

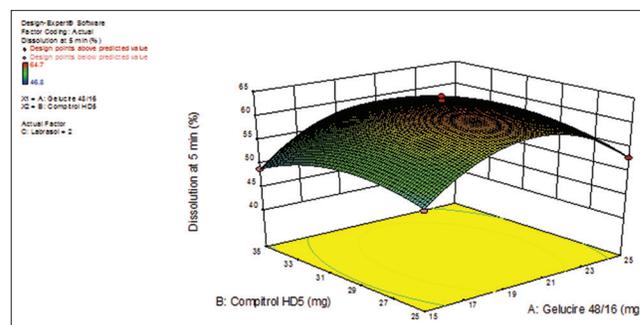

concentrations decrease the dissolution. On the other hand, at a lower level,  $Y_2$  decreased slightly when  $X_3$  increased from

**Table 5: Observed and predicted values and analysis of variance parameters for the response  $Y_2$**

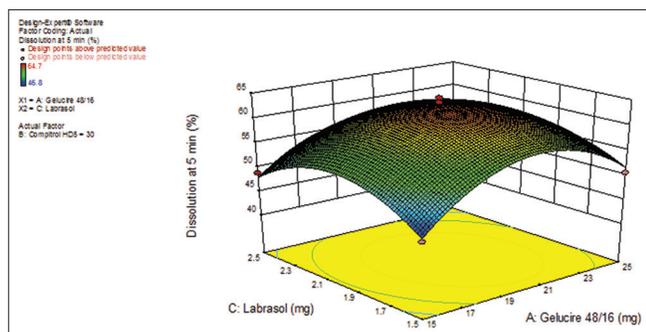

Figure 3: Response surface plots (three-dimensional) showing the effect of the amounts of Gelucire 48/16 ( $X_1$ ) and Labrasol ( $X_3$ ) on the response  $Y_2$  (Dissolution at 5 min)

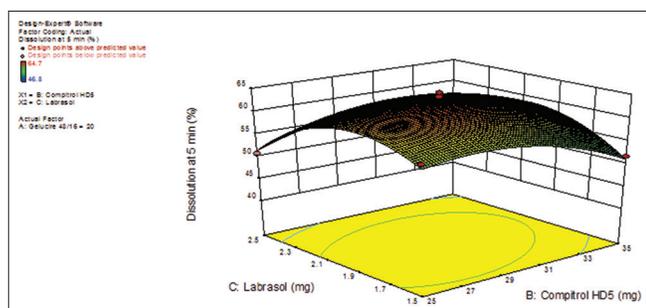

Figure 4: Response surface plots (three-dimensional) showing the effect of the amounts of Compitrol HD5 ( $X_2$ ) and Labrasol ( $X_3$ ) added on the response  $Y_2$  (dissolution after 5 min)

1.5 to 2.5 mg, the reason may be Labrasol is a liquid in nature and the concentration at higher level the power obtained not free flowing and the particles obtained in a coarser.

The predicted value of  $Y_2$  was 64.70% at  $X_1$ ,  $X_2$ , and  $X_3$  levels of 20.0, 30.0 and 2.0 mg, respectively.

## CONCLUSIONS

Box–Behnken design was successfully utilized to optimize the dissolution of rivaroxaban, a water-insoluble drug,

from lipid solid dispersion containing Gelucire 48/16 ( $X_1$ ), Compitrol HD5 ( $X_2$ ) and Labrasol ( $X_3$ ). All the independent variables were found to affect the dissolution of rivaroxaban from the resultant lipid solid dispersion either through linear, quadratic or interaction effects. The optimum formulation prepared provided rivaroxaban dissolution of 64.7% at 5 min. Consequently, through the rigorous analysis of the three independent variables and its effects on the investigated response, this study demonstrated the potential of Box–Behnken design in developing lipid solid dispersion.

## ACKNOWLEDGMENTS

The author would like to sincerely gratitude to the MSN Laboratories Pvt. Ltd, Hyderabad, for providing drug. I also thankful to Gattefosse Products, Mumbai, for providing lipid excipients.
